SPECIFICATION

IMPROVED BLACK MATRIX FOR
FLAT PANEL FIELD EMISSION DISPLAYS

STATEMENT OF GOVERNMENT INTEREST

This invention was made with Government support under Contract No. DABT63-93-C-0025 awarded by Advanced Research Projects Agency (ARPA). The Government has certain rights in this invention.

BACKGROUND OF THE INVENTION

The present invention relates to an improved flat panel display. More particularly, the present invention relates to an improved flat panel display such as a field emission display and a black matrix which improves image quality of the flat panel display.

Cathode ray tube (CRT) displays, such as those commonly used in desk-top computer screens, function as a result of a scanning electron beam from an electron gun impinging on phosphors of a relatively distance screen. The electrons increase the energy level of dopant(s) in the phosphors. When the dopant(s) return to their normal energy level, they release energy from the electrons as photons of light, which is transmitted through the glass screen of the display to the viewer.

One major disadvantage with CRT displays is that the CRT screen must be spaced from the electron gun by a relatively long distance. Moreover, CRTs typically consume relatively large amounts of power in

operation. Thus, a CRT is not suited for use in small, portable devices -- particularly those which operate under battery power.

Flat panel display technology is becoming increasingly important in appliances requiring lightweight portable screens. Currently, such screens typically use electroluminescent, liquid crystal, or plasma display technologies. Field emission devices represent a promising flat panel display technology which utilizes an array of cold cathodes or field emitter tips to excite pixels of phosphors on a screen. As an example, a field emission display may utilize a matrix-addressable array of cold cathodes which is selectively operated to activate particular picture segments. Field emission displays seek to combine the advantages of cathodoluminescent-phosphor technology with integrated circuit technology to create thin, high resolution displays wherein each pixel is activated by its own electron emitter.

Field emission devices generally include a baseplate assembly and an opposed faceplate. The faceplate has a cathodoluminescent phosphor coating that receives a patterned electron bombardment from the opposing baseplate, thereby providing a light image which can be seen by a viewer. The faceplate is separated from the baseplate by a vacuum gap, and outside atmospheric pressure is prevented from collapsing the two plates together by support columns. These support columns are often referred to as spacers. Arrays of electron emission sites (emitters) typically include a plurality of sharp cones that produce electron emission in the presence of an intense electric field. In the case of most field emission displays, a positive voltage is applied to an extraction grid relative to the sharp emitters to

provide the intense electric field required for generating cold cathode electron emissions. Typically, FEDs are operated at anode voltages well below those of conventional CRTs.

The faceplate of a field emission display operates on the principle of cathodoluminescent emission of light. A color image can be obtained using a color sequential approach sometimes referred to as spatial integration. Nearly all commercially successful color displays today employ spatial integration to provide a color image to the viewer. A common way to employ spatial integration is to provide red, green, and blue pixels which are addressed in the form of R/G/B triads. The intensity of each of the color dots within the triad is adjusted relative to one another to produce a range of colors within the triangular boundary formed by the color coordinates of the R, G, and B dots as depicted on the 1931 or 1976 C.I.E. chromaticity diagram. During viewing, the human eye integrates the spatially separated R/G/B dots into a perceived color image.

Spatial color displays may include a dark region separating the red, green, and blue patterned dots. For optimal performance, this region should be black. A major advantage of this region, referred to as the black matrix (although not necessarily black), is improved contrast of the display in ambient light. When a black matrix is employed on the faceplate it absorbs ambient incident light, thereby improving the contrast performance of the display. The use of a black matrix or "grille" in a CRT is described, for example, in U.S. Patent No. 4,891,110, issued January 2, 1990 to Libman et al., which is hereby incorporated by reference in its entirety.

As noted above, display technology such as CRTs consume relatively large amounts of energy. However, applications such as portable battery-operated computer displays put a premium on lower power consumption. Displays for other portable devices, such as portable stereos, electronic diaries, electronic telephone directories, and the like, also require low power consumption. Moreover, with available software features and consumer preferences, it is also desirable to provide portable devices with the ability to display color images.

Accordingly, there is a need for a flat panel color display having good contrast and reduced power consumption. Since flat panel field emission displays will become important in portable appliances that rely on portable power sources, there is a need to minimize the power consumption required by such displays. The present invention provides a field emission device which can provide color images having good contrast in a display having reduced power consumption.

BRIEF SUMMARY OF THE INVENTION

In accordance with one aspect of the present invention, a black matrix for a flat panel cathodoluminescent display, such as a field emission device, is formed from a substantially insulative material. An exemplary embodiment of the present invention includes a screen having a phosphor coating and an opposed emission source which selectively excites portions of the phosphor coating to generate visible light. The opposed emission source may include, for example, an array of conical field emitter cathodes.

The black matrix may be formed, for example, from praseodymium-manganese oxide (PrMnO_3).

A flat panel field emission device in accordance with the present invention may include a faceplate having a screen with phosphors and an insulative black matrix provided thereon. A baseplate includes a plurality of electron emission cathode tips arranged in an array and a lower potential extraction grid. The electron emission cathode tips may be selectively operated with row and column control signals to excite particular portions of the phosphors on the screen. Alternatively, the cathode tips may be addressed by row control signals, and columns in the extraction grid may be selected by column control signals to excite the particular portions of the screen phosphors. Additionally, the screen may include an addressable matrix of anode electrodes which are operated with row and column control signals.

BRIEF DESCRIPTION OF THE DRAWINGS

The objects, features, advantages and characteristics of the present invention will become apparent from the following detailed description of an exemplary embodiment, when read in view of the accompanying drawings, wherein:

FIGURE 1A is an illustrative cross-sectional schematic drawing of a flat panel field emission display;

FIGURE 1B is an illustrative perspective view of the flat panel field emission display of FIGURE 1A;

FIGURE 2 is a simplified perspective view of a conventional grid and emitter base electrode structure in a flat panel field emission display;

FIGURE 3A illustrates a drive circuit for a flat panel field emission display which utilizes an alternative grid and emitter base electrode structure;

FIGURE 3B illustrates a modification of the drive circuit of FIGURE 3A; and

FIGURE 3C is a top plan view of a layout for a flat panel field emission display architecture in which the drive circuits of FIGURES 3A or 3B may be used.

DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

The present invention is described in the context of exemplary embodiments. However, the scope of the invention is not limited to the particular examples described in the specification. Rather, the description merely reflects what are currently considered to be the most practical and preferred embodiments, and serves to illustrate the principles and characteristics of the present invention. Those skilled in the art will recognize that various modifications and refinements may be made without departing from the spirit and scope of the invention.

FIGURE 1A is a cross-sectional schematic of a portion of a flat panel field emission display. In particular, a single display segment 2 is depicted. Each display segment is capable of displaying, for example, a pixel of information or a portion of a pixel. A field emission display base assembly 4 includes a patterned conductive material layer 6 provided on a base 8 such as a soda lime glass substrate. The conductive material layer 6 may be formed, for example, from doped polycrystalline silicon and/or an appropriate conductive metal such as chromium. The conductive material layer 6 forms base electrodes and conductors for the field emission device.

Conical micro-cathode field emitter tips 10 are constructed over the base 8 at the field emission cathode site. A base electrode resistive layer (not shown) may be provided between the conductive material layer 6 and the field emitter tips 10. The resistive layer may be formed, for example, from silicon which has been doped to provide an appropriate degree of resistance. The resistive layer may operate as a lateral resistor wherein the direction of current flow from the base conductor 6 to the emitter tips 10 is primarily lateral. This arrangement helps reduce the likelihood of pinhole shorts through the resistive layer. Alternatively, a vertical resistor could be provided, in which case the field emitter tips 10 would be vertically aligned over the base conductor 6, and current flow would be primarily vertical.

A low potential anode gate structure or extraction grid 12 formed, for example, of doped polycrystalline silicon is arranged adjacent the field emitters 10. An insulating layer 14 separates the extraction grid 12 from the base electrode conductive material layer 6. The insulating layer 14 may be formed, for example, from silicon dioxide.

Proper functioning of the emitter tips requires operation in a vacuum. Thus, a plurality of support columns 16 are provided over the base assembly 4 to support a display screen 18 against atmospheric pressure. The support columns 16 are commonly referred to as "spacers." The spacers 16 may be formed in a number of conventional ways. Appropriate techniques for forming the spacers 16 are disclosed, for example, in U.S. Patent No. 5,205,770 issued April 27, 1993 to Lowrey et al., U.S. Patent No. 5,232,549 issued August 3, 1993 to Cathey et al., U.S. Patent No. 5,484,314 issued January 16, 1996 to Farnworth, and U.S. Patent No. 5,486,126 issued January 23, 1996. Each of these patents is hereby incorporated by reference in its entirety.

In operation, the display screen 18 acts as an anode so that field emissions from the emitter tips 10, represented by arrows 20, strike phosphor coating 22 on the screen 18. A black matrix 23 is formed on the screen 18 to improve image contrast. The field emissions from the emitter tips 10 excite the phosphor coatings 22 to generate light. A field emission is produced from an emitter tip when a voltage controller 24 establishes a voltage differential between the emitter tip and the anode structures. Thus when a group of emitter tips is activated, electrons are accelerated toward the phosphor coated transparent plate of the screen, which serves as an anode and has a positive voltage relative to the activated emitters. The phosphor on the screen is induced into cathodoluminescence by the bombarding electrons arriving at the phosphor surface, and serves as the emissive light source seen by a viewer.

A large number of suitable phosphors are known in the art. However, not all phosphors are recommended for use in field emission devices because the cathodes are in relatively close proximity to the coatings and may be sensitive to electronegative chemicals arriving on the cold cathode emitter surfaces. These surfaces can absorb the chemicals, thereby increasing the work function value and requiring higher operating voltages. This is undesirable in portable devices. Accordingly, the most preferred phosphors for use in a field emission device include, for example, ZnO:Zn, $Y_3(Al, Ga)_5O_{12}:Tb$, $Y_2SiO_5:Ce$, $Y_2O_3:Eu$, $Zn_2SiO_4:Mn$, $ZnGa_2O_4$ and $ZnGa_2O_4:Mn$. Except for ZnO:Zn and $ZnGa_2O_4$, these phosphors tend to be dielectric in nature. As a consequence, the typical threshold voltage needed to excite the phosphor tends to be relatively high (e.g., approximately 500 V to 2000 V). However, the threshold voltage may be reduced in a known manner by adding conducting materials such as non-luminescent zinc oxide or indium tin oxide powders to the phosphors before application to the screen.

It has been found that during operation a charge builds up on phosphors which are nonconductive or semi-conductive. The incident electrons on the phosphors surface are reflected, scattered, or absorbed by the phosphor. Furthermore, if the energy of these incident electrons is greater than a few tens of eV, then they can create a large number of secondary electrons within the phosphor screen. Some of these secondary electrons can escape back into the vacuum provided they have sufficient energy to overcome the work function of the phosphor surface. This can lead to the floating surface of the phosphor to shift its potential when the number of incident electrons is not equal to the number of secondary

electrons escaping from the surface. The negative charge built up on the phosphor screen, by reducing its potential, seriously diminishes the light output, leading to an unstable emission. Thus, it is desirable to have some degree of conductivity in the phosphors.

Referring now to the perspective view of FIGURE 1B, the phosphor coating may provide a number of segments useful in presenting a color image using an R/G/B diode. In particular, the phosphors may be arranged to provide a red picture segment 22R, a green picture segment 22G, and blue picture segment 22B which form a triangular layout. The black matrix 23 preferably forms a grid-like structure which separates the individual color picture segments. It is not necessary that the color segments be in the particular arrangement illustrated in FIGURE 1B. For example, the individual color segments could be arranged in common rows or columns (e.g., a row of green phosphors arranged between a row of red phosphors and a row of blue phosphors). Such an alternative arrangement may be advantageous, for example, in a field emission device which employs a switched anode scheme.

Various techniques are known in the art for allowing selectable activation of a display segment. For example, the grid 12 and screen 18 illustrated in Figures 1A and 1B could be held at a constant voltage potential and emitter tips selectively switched through column and row signals. In such an arrangement, the patterned conductive material 6 which forms the cathode base electrodes is arranged as a matrix that is addressable through column and row control signals. Alternatively, the base electrode conductors could be arranged in rows and the grid 12 arranged in columns

perpendicular to the rows of cathode base electrodes. Row control address signals to the cathode base electrodes and column control address signals to the grid column segments selectably activate display segments. Finally, the cathodes could be held at a constant voltage potential and a switched anode scheme utilized for the display screen 18. In a switched anode scheme, the faceplate conductor may include an addressable matrix of electrodes corresponding to individual picture segments.

Turning now to FIGURE 2, in one example the conductive material layer 6 may include a series of rows 6A, 6B and 6C, and the grid electrode 12 may include a series of columns 12A, 12B and 12C. It should be appreciated that FIGURE 2 is merely illustrative and, in practice, many more rows and columns would typically be provided for a display screen. Each picture segment in this example includes a 4x4 group of micro-cathode emitter tips 10. The redundancy in cathodes improves picture resolution and enhances product reliability and manufacturing yield.

To drive a particular picture segment, the controller selects a conductive material layer row (row 6C for example) and a grid electrode column (column 12A for example) and connects them respectively to appropriate voltage potentials. In this way, the picture segment corresponding to the cathodes located at the intersection of row 6C and column 12a will be activated. Suitable pixelator drive circuitry for the rows and columns is known in the art and is disclosed, for example, in commonly-owned U.S. Patent No. 5,438,240, issued August 1, 1995 to Cathey et al., and U.S. Patent No. 5,410,218, issued April 25, 1995 to Hush, which are hereby incorporated by reference in their entirety.

As previously noted, in a different arrangement the conductive material 6 which forms the base electrodes may form a matrix of addressable nodes and provide for both row and column controls for addressing the field emitters. In such an arrangement, the patterned conductive material layer 6 preferably provides a matrix of base electrodes under the individual picture segments. The conductive grid 12 is preferably continuous throughout the entire display and is maintained at a constant potential V_{GRID} . Drive circuits for use with such an arrangement are disclosed, for example, in commonly-owned U.S. Patent No. 5,357,172, issued October 18, 1994 to Lee et al, U.S. Patent No. 5,387,844, issued February 7, 1995 to Browning, and U.S. Patent No. 5,459,480, issued October 17, 1995, to Browning et al. These patents are hereby incorporated by reference in their entirety.

A single emitter node is illustrated in FIGURE 3A. Although the example emitter node depicted by FIGURE 2 has only three field emitter tips (10A, 10B, 10C), the actual number may be much higher. Each of the emitter tips 10 is electrically coupled to a base electrode 6' that is common to only the emitters of a single emitter node. To induce field emission, base electrode 6' may be operated in a pull-down mode. In the preferred embodiment, the base electrode 6' is maintained at ground potential through a pair of series-coupled field-effect transistors Q_C and Q_R . Transistor Q_C is gated by a column line control signal S_C from controller 24, while transistor Q_R is gated by a row line control signal S_R . When one of the transistors Q_C and Q_R is switched OFF, electrons continue to be discharged from the corresponding emitter tips until the voltage differential between

the base electrode 6' and the grid 12 drops below the emission threshold voltage. At that point, the display segment is turned OFF.

FIGURE 3B illustrates a modification of the arrangement of FIGURE 3A, wherein a current limiting field effect transistor Q_L having a threshold voltage V_T has been added. Both the drain and gate of transistor Q_L are directly coupled to grid 12. The channel transistor Q_L is sized such that current is limited to a minimal amplitude necessary to restore base electrode 6' and associated emitters 10A, 10B and 10C, to a potential that is substantially equal to $V_{GRID} - V_T$ at a rate sufficient to ensure adequate gray scale resolution.

A fusible link FL may be provided in the arrangements of FIGURES 3A and 3B. The fusible link FL may be blown during testing if a base-to-emitter short is detected within that emitter group, thus isolating the shorted group from the remainder of the array to improve yields and to minimize array power consumption.

Referring now to FIGURE 3C, a simplified layout is depicted which provides for multiple emitter nodes for each row-column intersection of the display array. The conductive material layer 6 includes a pair of doped polycrystalline silicon row lines R_0 and R_1 which orthogonally intersect metal column lines C_0 and C_1 and a pair of metal ground lines GND_0 and GND_1 . Ground line GND_0 is associated with column line C_0 , while ground line GND_1 is associated with column line C_1 . For each row and column intersection, there is at least one row line extension, which forms the gates and gate interconnects for multiple emitter nodes within that pixel. For

example, extension E_{00} is associated with the intersection of row R_0 and column C_0 ; extension E_{01} is associated with the intersection of row R_0 and column C_1 ; extension E_{10} is associated with the intersection of row R_1 and column C_0 ; and extension E_{11} is associated with the intersection of row R_1 and column C_1 . As all intersections function in an identical manner, only the components with the R_0 - C_0 intersection region will be described in detail.

Three emitter nodes, EN_1 , EN_2 and EN_3 , are supported by the R_0 - C_0 intersection region. Each emitter node comprises a first active area AA_1 and a second active area AA_2 . A metal ground line GND makes contact to one end of first active area AA_1 at first contact CT_1 . In combination with first active area AA_1 , a first L-shaped doped polycrystalline silicon strip S_1 forms the gate of field-effect transistor Q_C (see FIGURES 3A and 3B). Metal column line C_0 makes contact to doped polycrystalline silicon strip G_1 at second contact CT_2 . Doped polycrystalline silicon extension E_{00} forms the gate of field-effect transistor Q_R (see FIGURES 3A and 3B). A first metal strip MS_1 interconnects first active area AA_1 and second active area AA_2 , making contact at third contact CT_3 and fourth contact CT_4 , respectively. The portion of metal strip MS_1 between third contact CT_3 and fourth contact CT_4 forms fusible link FL. The emitter base electrode 6' (not shown in FIGURE 3C, see item 6' in FIGURES 3A and 3B) is coupled to metal strip MS_1 . A second L-shaped doped polycrystalline silicon strip S_2 forms the gate of current limiting transistor Q_{CL} , and a second metal strip MS_2 is connected to second doped polycrystalline silicon strip S_2 at fifth contact CT_5 , and to second active area AA_2 at sixth contact CT_6 . The grid plate (not shown in FIGURE 3C, see FIGURES 3A and 3B) is

connected to second metal strip MS₂. Of course, other conductive materials may be substituted for the doped polycrystalline silicon and metal structures. For example, silicided polysilicon or molybdenum may be used.

Various techniques are known for producing structures such as those illustrated in FIGURES 1-3. For example, techniques for forming the conical cathode emitter tips are disclosed in commonly-owned U.S. Patent No. 5,151,061, issued September 29, 1992 to Sandhu, U.S. Patent No. 5,330,879, issued July 19, 1994 to Dennison, U.S. Patent No. 5,358,908, issued October 25, 1994 to Reinberg et al., U.S. Patent No. 5,391,259, issued February 21, 1995 to Cathey et al., and U.S. Patent No. 5,438,259 issued August 1, 1995 to Cathey et al. Each of these patents is hereby incorporated by reference. In addition to the foregoing techniques, conventional methods such as the Spindt process for producing conical field emitters are well-known in the art. Processes for producing field emitters are disclosed, for example, in Spindt et al. U.S. Patent No. 3,665,241, issued May 23, 1972, No. 3,755,704, issued August 28, 1973, and No. 3,812,559, issued May 28, 1974.

Overall techniques for producing the base assembly are known, for example, from U.S. Patent No. 5,186,670, issued February 16, 1993 to Doan et al. and U.S. Patent No. 5,372,973, issued December 13, 1994 to Doan et al. The techniques disclosed in those patents utilize a mechanical planarization technique such as chemical-mechanical planarization following creation of the layers which make up the base assembly. Each of these patents is hereby incorporated by reference in its entirety.

In a preferred exemplary embodiment, the black matrix is formed from praseodymium-manganese oxide (PrMnO_3) having an appropriately high molar ratio of praseodymium to manganese (Pr:Mn). The molar ratio is selected to ensure that the black matrix material is highly resistive. This can be accomplished by reducing the amount of manganese relative to praseodymium, thereby decreasing conductivity. The praseodymium-manganese oxide material may be made by combining Pr_6O_{11} with MnO_2 or MnCO_3 in a mill jar and milling the combination to a powder containing particles having an average diameter of approximately 2 μm . The powder may then be heated at a temperature ranging from 1200° C to 1500° C, and preferably from 1250° C to 1430° C, for about 4 hours. As a result, the material takes on a very dark matte black color. The powder is thereafter re-crushed and milled to yield a powder having about a 2 μm average particle size. The Pr:Mn ratio in the resulting material may be controlled by adjusting the relative amounts of Pr_6O_{11} and MnO_2 or MnCO_3 in the starting materials.

The praseodymium-manganese oxide material may be deposited on the screen using conventional techniques well-known in the art. For example, RF sputtering, laser ablation, plasma deposition, chemical vapor, deposition or electron beam evaporation may be utilized. Appropriate operating parameters used in the foregoing techniques are readily within the skill in the art, and need not be detailed here.

Prior to deposit of the black matrix material, the screen may be patterned with a photoresist in a known manner to expose only those areas of the screen on which the black matrix is to be deposited. The photoresist

may then be removed following deposition of the black matrix material. A second photoresist may then be patterned to expose only those areas of the screen on which the phosphor is to be deposited, followed by depositing phosphor in the exposed areas. If desired, an appropriate binder may be applied and the screen baked, as is known in the art.

As an alternative, a uniform layer of PrMnO_3 may be provided on the screen. An appropriate etching technique may then be utilized to remove portions of the PrMnO_3 layer that do not correspond to the black matrix, as understood in the art. Of course, other appropriate techniques known in the art may be utilized as well.

As noted above, the praseodymium-manganese oxide material used in the black matrix is selected to be highly resistive, and therefore acts as an insulator. For low voltage operations, it is beneficial to have the areas around the pixels be insulated so that electrons go to the phosphors rather than being drained by non-light emissive materials of the black matrix. Such a drain wastes emitted electrons and increases power consumption, which would be a notable drawback for battery operated devices in particular. Furthermore, if a screen anode switching scheme is utilized to selectively activate the pixels, as discussed above, an insulative black matrix material alleviates possible problems associated with electrical shorting between the pixels. Such short circuits, of course, degrade or completely ruin the quality of any displayed image.

Although the invention has been described in connection with what is presently considered to be the most practical and preferred embodiments,

WHAT IS CLAIMED IS:

1. A flat panel field emission display comprising:
a screen having a phosphor coating;
an emission source opposite said screen which selectively excites portions of said phosphor coating to generate visible light; and
a black matrix provided on said screen, said black matrix being formed of a substantially insulative material.
2. The display of claim 1, wherein said black matrix is formed from praseodymium-manganese oxide.
3. The display device of claim 1, wherein said emission source includes an array of field emitter tip cathodes.
4. The display of claim 3, wherein said emission source further includes a low potential extraction grid provided adjacent said field emitter tip cathodes.
5. The display of claim 4, wherein said array of field emitter tips is formed in matrix addressable by row select control signals.
6. The display of claim 5, wherein said extraction grid is a continuous electrode, and wherein said field emitter tip matrix is further addressable by column select control signals.

7. The display of claim 5, wherein said extraction grid includes a plurality of column electrodes addressable by column select control signals.

8. The display of claim 4, wherein said extraction grid is held at a substantially constant low potential value and said field emitter tips are held at a substantially constant potential value higher than said low potential value, and said screen includes a matrix of anode electrodes which are addressable by row and column control signals.

9. The display of claim 1, wherein said display provides color images and wherein said black matrix improves image contrast.

10. A flat panel field emission display, comprising:
a faceplate including a screen, phosphors provided on said screen, and a black matrix provided on said screen;
a baseplate assembly including a plurality of electron emission cathode tips arranged in an array and a low potential extraction grid;
wherein said black matrix is formed from a substantially insulative material.

11. The field emission display of claim 10, wherein said black matrix material is PrMnO_3 .

12. The field emission display of claim 10, wherein said low potential gate is a continuous electrode, and wherein said field emitter tip matrix is further addressable by column select control signals.

13. The field emission display of claim 12, wherein said low potential gate includes a plurality of column electrodes addressable by column select control signals.

14. The field emission display of claim 12, wherein said low potential gate is held at a substantially constant low potential value and said field emitter tips are held at a substantially constant potential value higher than said low potential value and said screen includes a matrix of anode electrodes which are addressable by row and column control signals.

15. A method of making a flat panel field emission display comprising the steps of:

providing a phosphor coating on a display screen;

arranging an emission source opposite said display screen for selectively exciting portions of said phosphor coating to generate visible light during subsequent operation; and

providing a black matrix on said screen, said black matrix being formed of a substantially insulative material.

16. The method of claim 15, wherein said black matrix is formed from praseodymium-manganese oxide.

17. The method of claim 16, wherein said praseodymium-manganese oxide is prepared by combining selected amounts of Pr_6O_{11} with a material selected from the group including MnO_2 and MnCO_3 ; and heating the resulting combination at a temperature ranging from approximately 1200°C to 1500°C .

18. The method of claim 17, wherein said heating temperature ranges approximately from 1250°C to 1430°C.

19. The method of claim 18, wherein the resulting combination is heated for approximately four hours at the heating temperature.

20. The method of claim 17, wherein the resulting combination is heated for approximately four hours at the heating temperature.

21. The method of claim 17, including the further step of milling the resulting combination subsequent to said heating step to yield a powder having about a 2 μm average particle size.

22. The method of claim 16, wherein said black matrix forming step includes patterning a photoresist material on said screen to expose only those areas of the screen on which the black matrix is to be deposited; depositing said praseodymium-manganese oxide; and removing said photoresist material.

23. The method of claim 22, wherein said step of providing a phosphor coating is performed subsequent to said black matrix forming step and includes patterning a second photoresist material to expose only those areas of the screen on which said phosphor coating is to be provided; depositing said phosphor coating; and removing said second photoresist material.

24. The method of claim 16, wherein said black matrix forming step includes providing a uniform layer of praseodymium-manganese oxide on said display screen and selectively etching portions of said uniform layer which do not correspond to said black matrix.

25. The method of claim 15, wherein said emission source arranging step arranges an array of field emitter tip cathodes opposite said display screen.

26. The method of claim 25, including the further step of providing a low potential extraction grid adjacent said field emitter tip cathodes.

27. the method of claim 26, wherein said low potential extraction grid is formed from a continuous electrode.

665290-8566E60

ABSTRACT OF THE DISCLOSURE

A flat panel field emission device includes a black matrix formed from an electrically insulative material such as praseodymium-manganese oxide. The insulative black matrix increases image contrast and reduces power consumption. For field emission devices which utilize a switched anode for selectively activating pixels, the insulative material reduces or eliminates problems associated with short circuiting of the pixels.

RULE 63 (37 C.F.R. 1.63)
DECLARATION AND POWER OF ATTORNEY
FOR PATENT APPLICATION
IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

As a below named inventor, I hereby declare that my residence, post office address and citizenship are as stated below next to my name, and I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

IMPROVED BLACK MATRIX FOR FIELD EMISSION DISPLAYS

the specification of which (check applicable box(es)):

- ☒ is attached hereto
☐ was filed on _____ as U.S. Application Serial No. _____ (Atty Dkt. No. 2146-4)
☐ was filed as PCT International application No. _____ on _____
and (if applicable to U.S. or PCT application) was amended on _____

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above. I acknowledge the duty to disclose information which is material to the patentability of this application in accordance with 37 C.F.R. 1.56. I hereby claim foreign priority benefits under 35 U.S.C. 119/365 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed or, if no priority is claimed, before the filing date of this application:

Priority Foreign Application(s):

Application Number	Country	Day/Month/Year Filed
--------------------	---------	----------------------

I hereby claim the benefit under 35 U.S.C. §119(e) of any United States provisional application(s) listed below.

Application Number	Date/Month/Year Filed
--------------------	-----------------------

I hereby claim the benefit under 35 U.S.C. 120/365 of all prior United States and PCT international applications listed above or below and, insofar as the subject matter of each of the claims of this application is not disclosed in such prior applications in the manner provided by the first paragraph of 35 U.S.C. 112, I acknowledge the duty to disclose material information as defined in 37 C.F.R. 1.56 which occurred between the filing date of the prior applications and the national or PCT international filing date of this application:

Prior U.S./PCT Application(s):

Application Serial No.	Day/Month/Year Filed	Status: patented pending, abandoned
------------------------	----------------------	--

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon. And I hereby appoint **NIXON & VANDERHYE P.C., 1100 North Glebe Rd., 8th Floor, Arlington, VA 22201-4714, telephone number (703) 816-4000 (to whom all communications are to be directed)**, and the following attorneys thereof (of the same address) individually and collectively my attorneys to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith and with the resulting patent: Arthur R. Crawford, 25327; Larry S. Nixon, 25640; Robert A. Vanderhye, 27076; James T. Hosmer, 30184; Robert W. Faris, 31352; Richard G. Besha, 22770; Mark E. Nusbaum, 32348; Michael J. Keenan, 32106; Bryan H.
